ABSTRACT OF THE DISCLOSURE

A surgical process for removing the third phalanx of a feline, and most commonly a housecat, while reducing bleeding, swelling, pain and tissue deficit. A circumferential incision is formed on the epidermis of the 5 unguial crest and traction is applied to the epidermis in a cranial direction. This exposes the extensor tendon and synovium, which are incised by the laser from a dorsal position aimed in a palmar direction. While applying traction to the third phalanx in a palmar direction, the 10 collateral ligaments are ablated, permitting further disarticulation of the PII-PIII joint. Finally, the flexor tendon and tissue of the pad are incised by the laser from a dorsal position, permitting removal of the third phalanx. The declaw site is then covered with the redundant 15 epithelium preserved in this process.
